# MATH547: Stochastic Processes

Matthew He

January 14, 2025

Abstract

#### 1 Preliminaries

### **Definition 1** (Probability space).

# 1.1 Independence

Probability theory is about finding some sort of independence.

### Definition 2 (Independence).

### Independence of Events

Events  $A_1, A_2, A_3, ..., A_n$  are independent if and only if: For any collection  $I \subseteq \{1, 2, ..., n\}$ 

$$P\left(\bigcap_{j\in I}A_j\right)=\prod_{j\in I}P(A_j).$$

### Independence of Random Variables

For random variables  $X_1, X_2, ... X_n$ , taking values in state spaces  $S_1, S_2, ... S_n$ , these are independent if and only if: for any  $E_1 \subseteq S_1, E_2 \subset S_2, ... E_n \subset S_n$  the events  $A_j = \{X_j \in E_j\}$  for  $1 \le j \le n$  are independent.

# 1.2 Convergences and limit theorems

#### **Definition 3** (In-probability convergence).

The sequence  $(X_j: j \in \mathbb{N}_0)$  converges in-probability to  $X_0$  if for all  $\epsilon > 0$ ,

$$\lim_{j\to\infty}P(d(X_j-X_0)>\epsilon)=0,$$

in which case we write  $X_j \xrightarrow[j\to\infty]{\Pr} X_0$ .

**Theorem 1** (Law of large number (weak)). If  $\{X_n\}_{n=0}^{\infty}$  are real-valued, independent, identically distributed random variables and  $\mathbb{E}(X_i) = \mu < \infty$ , then

$$\frac{1}{n} \sum_{j=1}^{n} X_j \to_{n \to \infty}^{\mathbb{P}} = \mathbb{E}(Xi)$$

### **Definition 4** (Almost sure convergence).

The sequence  $(X_i : j \in \mathbb{N}_0)$  converges almost surely to  $X_0$  if

$$\Pr\left(\limsup_{j\to\infty}d(X_j,X_0)>0\right)=0,$$

in which case we write  $X_j \xrightarrow[j\to\infty]{\text{a.s.}} X_0$ .

*In-probability convergence does not rule out rare events.* 

It is generally the case that in-probability convergence is strictly weaker than almost sure convergence.

If  $\{X_n\}_{n=0}^{\infty}$  are real-Theorem 2 (Law of large number (strong)). valued, independent, identically distributed random variables and  $\mathbb{E}(X_i) = \mu < \infty$ , then

$$\frac{1}{n} \sum_{j=1}^{n} X_j \to_{n \to \infty}^{a.s.} = \mathbb{E}(Xi)$$

### Example 1 (In-probability v.s. almost sure convergence)

Suppose  $\{X_i\}^{\infty}$  be independent  $\{0,1\}$  - valued random variables.

$$P(X_j = 1) = 1/j$$

In this case, we have

$$\lim_{i \to \infty} P(\left| X_j - 0 \right| > \epsilon) = P(X_j = 1) = 1/j = 0,$$

therefore  $X_j \xrightarrow[i \to \infty]{\Pr} 0$ . However,

$$P(\limsup_{j\to\infty} |X_j - 0| > 0) = P(\limsup_{j\to\infty} X_j = 1) = 1,$$

**Definition 5** (Weak convergence). The sequence  $(X_j : j \in \mathbb{N}_0)$  converges in law to  $X_0$  if for all bounded continuous functions  $\varphi: S \to \mathbb{R}$ 

$$\lim_{j\to\infty} \mathbb{E}\varphi(X_j) = \mathbb{E}\varphi(X_0),$$

in which case we write  $X_j \xrightarrow[i \to \infty]{\text{law}} X_0$ .

**Theorem 3** (Central limit theorem). If  $\{X_n\}_{n=0}^{\infty}$  are iid. random variables, with  $\mathbb{E}(X_i) = \mu < \infty$  and  $Var(X_i) = \sigma^2 < \infty$ , then  $\forall t \in \mathbb{R}$ ,

$$\lim_{n\to\infty} P\left(\frac{\sum_{j=1}^n X_j - n\mu}{\sigma\sqrt{n}} \le t\right) = \Phi(t)$$

where  $\Phi(t)$  is the standard normal distribution function.

The intuition behind the limsup here? Limsup always exist.

Large number theorem tells us value will converge to the expected value. Then central limit theorem tells us how close it will be.

# Conditional probability and expectation

**Definition 6** (Conditional expectation on random variables). If X takes countably many values and Y is a random variable with either  $Y \geq 0$  or  $\mathbb{E}|Y| < \infty$ , then,

$$\mathbb{E}[Y|X] = \sum_{X} \mathbb{E}[Y|X = x] \mathbb{1}(X = x)$$
$$= \sum_{X} \frac{\mathbb{E}[Y|\mathbb{1}(X = x)]}{P(X = x)} \mathbb{1}(X = x).$$

Or, in measure-theoretic terms, we have:

$$\mathbb{E}\left[Y|X\right] = \mathbb{E}\left[Y|\sigma(X)\right]$$

Another case where we can condition:

Definition 7 (Conditioning on families of independent random If  $(X_1, X_2, ..., X_n)$  are independent random variables in some state space S, and  $Y = f(X_1, X_2, ..., X_n)$  for  $f: S^n \mapsto \mathbb{R}$ 

# Stochastic Processes

A stochastic process is a family of random variables indexed by natural numbers (time).

Definition 8 (Stochastic process). A stochastic process is a collection of random variables  $\{X_t\}_{t\in\mathbb{N}_0}$  where t represents time.

**Definition 9** (Filtration). A filtration  $(\mathcal{F}_j: j \geq j_0)$  is a sequence of  $\sigma$ algebras with the property that they are increasing, so for all  $j \geq j_0$ ,  $\mathcal{F}_i \subseteq$  $\mathcal{F}_{j+1}$ . A stochastic process  $(X_j : j \geq j_0)$  is adapted to a filtration if  $X_j$ is  $\mathcal{F}_{j}$ -measurable for all  $j \geq j_0$ . Any stochastic process also gives rise to a filtration, its natural filtration, just by setting  $\mathcal{F}_i = \sigma(X_k : j_0 \le k \le j)$ .

**Definition 10** (Countable state space markov chain). A stochastic process  $\{X_j\}_{j\in\mathbb{N}_0}$  satisfies the Markov property.

 $\sigma$ -algebra is about information.
